Title : The Protective Role of Tissues of the Organism against  
its Own Denatured ProteinsOrig Pub : Zh. Mikrobiol., Epidemiol. i Immunobiol., 1957,  
No. 6, 104-111

Abstract : The formation of antibodies against the organism's own denatured proteins (AODP) has been demonstrated with the aid of the RSK [Blood Serum Reaction] in which the antigen was the animals' own serum proteins, partially denatured by three-hour heating at 60 degrees or a 24-hour exposure to the action of 50-percent alcohol. In animals with inflammation due to turpentine irritation (aseptic) or to staphylococci, the titer of AODP is higher the greater the inflammation and necrosis of the

Abstract : tissues. In a number of experiments the protective significance of the AODP was established; upon repeated administration of turpentine to the skin of guinea pigs, observation was made of the formation of AODP and a corresponding subsequent diminution in the size of the focus of inflammation and necrosis and a shortening of the healing time of the focus by an average of nine days following the second or third injection. Elevation of the resistance of mice upon repeated X-irradiation was also accompanied by the appearance of AODP in titers which were greater the higher the survival rate of the animals. Upon single irradiation of various parts of the body of mice with  $130^{\circ}$  r, there was a direct relationship between the percentage of surviving animals and the antibody titer. Immunisation of the mice with homologous denatured protein led to the formation of AODP in a titer of 1:50 (on the average) and to an increase of two times in the

**888 Experiences with Irradiation of Patients with Cerebral Tumours**

GALPERIN, M.D.  
Leningrad (Soviet Union)

At present, surgical as well as irradiation treatment are regarded as being the most effective therapy. The two methods occasionally prove to be highly beneficial.

The main requisite for the choice of either surgery or irradiation of tumours is early diagnosis. For the successful treatment of brain-tumours, the choice of the method is all important. The surgical and irradiation treatments are not competitive. Taking into consideration the position of the tumour, its extent, its biological structure, the characteristics of the clinical course and the general condition of the patient, preference should be given to one or the other method.

The author examined recent and past results of irradiation and combined irradiation and surgical treatment of brain-tumours during 1935-1951. 339 case-histories of patients of the Radiogeno-Radiological Department of the Pirogov Institute of Neuro-Psychology were evaluated.

Irradiation was performed on patients with tumours of varied localisation and of different histological structure. Comparative assessment of the results of the different methods of irradiation in the patients was carried out, depending on the histogenesis of the tumour.

Analysis of these case-histories indicates that the elaborated and applicable methods of irradiation of brain-tumours prolong considerably the life of the patients and have an immediate, marked curative effect.

The complications occurring during treatment as well as afterwards were also studied. Clinical indications and contra-indications of irradiation of patients with brain-tumours were elaborated.

**889 Effect of the Chronic Influence of Low Doses of Ionizing Irradiation**

on the Humoral and Cell-Linked Immunity in Animal Experiments  
KISELEV, P.N. & KISELEV, P.V.  
Leningrad (Soviet Union)

The authors investigated the changes in natural immunity and immunogenic processes in laboratory animals under chronic irradiation with low doses of ionizing radiation. The dose-performance of the irradiation was 1.0-1.5 r/day. The period of irradiation lasted from 30 days to 2.5 years. The total dose was 30-3,000 r. The effect of these irradiation doses led to the development of chronic radiation illness. On this basis the disorder in the humoral and cellular natural immunity and immunogenesis was investigated, with the following results:

1. Under chronic, uninterrupted action, lethal radiation disease develops through auto-infection. The total lethal dose exceeds the single dose by 2-4 times. Chronic radiation illness is preceded by negligible leucopenia, preceded by a phase of leucocytosis.

2. Under chronic, uninterrupted action, natural immunity and immunogenesis are reduced. Reduction of natural immunity appears after 8-10 months of chronic illness, due to reduction of bactericidal activity of the blood, leucocytes and reduction of phagocytic activity of the leucocytes. A change in the type of the complement was observed only as late as after 10-12 months. Bactericemia is preceded by reduced bactericidity of the blood.

3. The disturbance of cellular immunity is indicated by an increased sensitivity to toxins, by an enhanced reproduction of virus, by a lowering of the ingesta-trophic and digestive capability of the reticuloendothelial cells.

302

Presented at the Ninth International Congress of Radiology, Munich, 23-30 July 1959.

Xo. 411-MF

4. The most marked reduction of natural immunity occurs in young animals, born of irradiated parents and subjected during the period of lactation to the effect of irradiation.

5. Chronic irradiation of an organism leads to destruction of immunoglobulins. However, at an irradiation dose equal to a single one, the production of antibodies is less suppressed. These differences are connected with the adaptive mechanisms and reparative processes in the human organism to irradiation.

6. The phenomenon of suppression of natural immunity and immunogenesis may be reversed by a period of sleep stimulation. At a total dose of 300-1000 r, the following is observed: increase of bactericidity of the blood, increased phagocytic activity of the leucocytes, the cells of the reticuloendothelial system; reduction of sensitivity to toxins; stimulation of anti-body formation.

**890 Irradiation of Cancer of the Oral Cavity, the Nasopharynx, and the Antrum**

KROLOWA, A.W. & KOZLOVA, A.V.  
Moscow (Soviet Union)

Early results of the use of radioactive preparations (radium, radioactive cobalt, gold, thymolphosphate) in the treatment of 221 patients are presented. Among them 224 patients there were 47 with malignant tumours of the oral cavity, 35 with malignant tumours of the nasopharynx and 111 patients with malignant tumours of the antrum.

Generally the 1st and 2nd stages were found in 66 patients, stage 3 in 109 and stage 4 in 56 patients.

Treatment resulted in the combined method of ray therapy (radium surgery, cavity therapy, superficial therapy and plethysmotherapy).

The patients were under observation every 3-10 years. Recovery was observed in 44% of the patients with malignant tumours in all 4 stages.

In some of the patients irradiation was followed by complications. The methods and the results of treatment are discussed.

**891 Radiobiological Investigations and Rational Means of Reducing the Dose During These Investigations**

KOBEDINSKY, M.N.  
Leningrad (Soviet Union)

During recent years the natural level of radiation has risen continuously. One of the factors raising the level are the radio-diagnostic examinations, which according to reports from foreign authors, increase the amount of radiation acting on the population by 22% - 30%.

Particular attention should be given to the effect of radiation on the salivary glands. General regulars of radiation may never even with very low doses.

In X-ray exposures and fluoroscopy the lowest dose of the radiation striking the salivary glands may be 100-1,000 rads. The variations in dose depend on the conditions of radiation and also on the part of the body to which radiation is directed. The highest doses affecting the salivary glands occur in examinations of the pelvic region, the hip and the abdomen, especially when treated.

The necessity for an ever-increasing extension of radio-diagnosis for the population and the new methods of radiological examinations in practice, requires research both means for reducing the radiation dose acting on the salivary glands. X-ray protection in fluoroscopy, in order to reduce the radiation dose and in particular the radiation effect on the teeth, is required. Highly qualified staff to which the patient is addressed and replacement of the dose in the edge of the radiation field. The examinations should be performed with border rays, using heavier filtration and increased voltage, as well as short focal distance.

In fluoroscopy the following is required: Standardization of the rays of the examine, organization of the working hours and low amplitude. In addition, the advantages of working with screen savers should be made use of.

In radiological examination of the pelvic region, the hip and the abdomen, the ovaries must be protected from direct radiation.

(d) Changes in Cellular Immunity Under the Influence of Chronic Continuous Exposure to Relatively Small Doses of Ionizing Radiation

P. N. Klyukov and P. A. Bojatin

The influence of chronic continuous exposure to small doses of  $^{60}\text{Co}$   $\gamma$ -rays on the humoral and cellular immunity of the organism has been studied. The investigations were carried out on different experimental animals (mice, rats, guinea-pigs and rabbits). The dose rate varied from 0.5 to 3.5 r/day. Irradiation was protracted from 30 days to 5 yr. The total dose was 100-2000 r.

Such an exposure resulted in the development of chronic radiation disease manifested in different degrees. The observed changes in the humoral immunity were of a phasic type and manifested themselves in stimulation and subsequent inhibition which were accompanied by the development of auto-infectious processes.

The experiments have shown that chronic continuous exposure to small doses of ionizing radiation brings about a disturbance of the cellular immunity. These changes also are of a phasic type and characterized by the same regularities. The increase in the immunity is always less manifest than its subsequent inhibition. The decrease in the cellular immunity is expressed: (1) in reduction of function of the reticulo-endothelial system, occurring rather late also in the case of sufficiently large total doses; (2) in changes of absorbing and digesting functions of the leucocytes; (3) in increasing the sensitivity of the organism towards exo- and endo-toxins; and (4) in changing the capability of somatic cells to remove heterogeneous particles and to inhibit the growth of viruses. A certain stimulation of the organism preceding its weakening is revealed in a lesser delay of the growth of influenza virus in the organism, stimulation of a RES function and increasing the phagocytic capability of the leucocytes.

AUTHOR: Kisilev, P. N. and Buzini, P. A.

TITLE: Changes in cell immunity upon chronic continuous exposure to ionizing radiation

PERIODICAL: Meditsinskaya radiologiya, v. 7, no. 8, 1962, 59-65

TEXT: The effect of chronic ionizing radiation on the mechanism of immunity has not been sufficiently studied. This is the continuation of a previous study. Rabbits, guinea pigs, albino mice, and rats were subjected to an irradiation of 50-4000 r with Co<sup>60</sup> gamma rays at 0.5-4.3 r/24 hrs. The observations continued for 5 years. A dose of 465 r did not alter the properties of WBC, RES, and somatic cells. The phagocytosing and digesting properties of WBC were distorted after larger doses of irradiation and up to a dose of 700-1000 r there was a definite dependence between these factors. Irradiation during embryogenesis brought about the development of nonphagocytosing WBC, even after a total dose of 200 r. The RES function was studied with S<sup>35</sup>-labelled B. coli and collidal Au<sup>198</sup>. The RES function was evaluated by the method of Benacerraf, Halpern, et al. A chronic continuous irradiation at relatively small doses (2.4 r/24 hours) brings about a suppression of the RES function following a prior stimulation. The sensitivity of somatic cells to bacterial toxins and viruses was also altered in chronic continuous irradiation (950 r at 1.29 r/24 hrs). Sensitivity was estimated by determination of LD<sup>50</sup> in both control and experimental animals. The increased sensitivity X

Card 1/2

Changes in cell immunity ...

S/241/62/007/008/001/001  
I015/I215

of cells to endo- and exotoxins was preceded by a decreased sensitivity (up to a total dose of 285 r). Thus, chronic irradiation with small doses affects both the humoral and cellular immunity simultaneously and with the same characteristics. There are 2 figures and 4 tables.

AUTHOR: Kiselev, P. N. (Director); Sivertseva, V. N.TITLE: Change in capacity of irradiated animal tissues to destroy  
microbe toxins 19 63 62SOURCE: Meditinskaya radiologiya, no. 5, 1963, 33-39TOPIC TAGS: radiation sickness, microbe toxin, endotoxin, spleen,  
reticuloendothelial system, detoxicating mechanism

ABSTRACT: An organism with radiation injuries is highly sensitive to microbe toxins, particularly to endotoxins in tissues, because its detoxication mechanisms are impaired. Humoral factors are important in exotoxin destruction in the blood, but how can the endotoxins in tissues be destroyed? Sources in the literature have suggested that the reticuloendothelial system (15% of the body) may play an important role. This is a study of the effect of the reticuloendothelial system as represented by mice spleens on endotoxin destruction in tissues. Mice were subjected to sublethal doses of X-ray irradiation and spleen extracts were prepared. Dry endotoxin (S. Breslav type) was dissolved in extract solutions and incubated. Cortisone in Card 1/62

L 13066-63

ACCESSION NR: AP3000257

varying doses was used to stimulate the spleen. Results show that the spleen has a remarkable capacity for destroying endotoxins in pure form or in the form of microbe bodies. Spleen extract prepared from mice at the height of radiation sickness is two times less effective in destroying endotoxins than extracts from nonirradiated mice. Use of cortisone strengthens the detoxicating mechanisms and makes them more resistant to endotoxins (Figs. 4, 5, 6). The author concludes that the reticuloendothelial system's capacity to destroy endotoxins is apparently of an enzyme nature. Endotoxins can be destroyed in the tissues by activating natural detoxication mechanisms with cortisone (and probably other stimuli), but only to a certain degree because in advanced stages of radiation sickness the mechanisms are totally impaired. TITLE: Remote immunologic sequelae of the effect of ionizing radiation

SOURCE: Meditsinskaya radiologiya, no. 5, 1964, 50-58

TOPIC TAGS: immunologic sequelae, ionizing radiation, immunogenesis, immunity retention, *Salmonella enteridis* Gartneri, *Salmonella breslau*, *Pseudomonas aeruginosa*, endotoxin sensitivity, bacteremia, phagocytosis, delayed postirradiation infection, mononuclear phagocyte, polymnuclear phagocyte, infection resistance, antibody synthesis, vaccination

ABSTRACT: The duration of retention of natural immunity and immunogenesis acquired during acute radiation sickness was studied in guinea pigs and white mice which received 200 r ( $LD_{30/30}$  days) and 465-500 r ( $LD_{50/30}$ ) respectively. Resistance to infection was tested 3-28 months after irradiation, in either spontaneously infected animals or by infection with *Salmonella enteridis* Gartneri, *Salmonella breslau* or *Pseudomonas aeruginosa*. Endotoxin sensitivity was investigated by introducing

Card 1/4

ACCESSION NR: AP4038943

the endotoxin in a LD<sub>50/3 days</sub> dose and the bacteremia determined by microbial count in blood and organs. The number of leucocytes in peripheral blood, phagocytic activity in peritoneal exudate, etc. served as immunologic indicators. Spontaneous infection of the mice with *Salmonella enteridis Gartneri* after 5½ months led to the death of 58% irradiated against 18% of non-irradiated animals. Experimental infection with 100 million bodies of the same agent in 380 mice, half of which had been irradiated 6 months earlier, led to death of 72% of the irradiated, 38% of the control mice. *Salmonella breslau* infection under the same conditions yielded the corresponding figures of 97 against 65%. Spontaneous infection of guinea pigs with *Pseudomonas aeruginosa* 19 months after irradiation led to death of 32 against 14%. Experimental infection with the same agent in a group of mixed age was performed 3, 6, 9, 12, 19 and 28 months after irradiation. Increased sensitivity to infection (compared to controls) decreased only after the 19th month, to return to normal after 28 months. A study of the reasons for such increased sensitivity comprised testing the bactericidal property of the blood against *Salmonella typhi murium*, the complement titer, phagocytic activity of leucocytes, bacteremia in mice with acute and chronic radiation sickness, as well as in controls 6 months after irradiation. Microbe lysing activity was found decreased

Card 2/4

ACCESSION NR: AP4038943

despite close to normal counts. Similar studies with *Pseudomonas aeruginosa* in guinea pigs 3-28 months after irradiation showed e.g. a decrease in mononuclear and increase in polymorphonuclear phagocytes, their numbers returning to normal only after 28 months. Microbial count in guinea pig blood at various periods following irradiation confirmed the decreased phagocytic activity as late as 19 months after irradiation. Mouse sensitivity to *Salmonella typhi abdominalis* endotoxin was 2.6 times that of controls after 2½ months, 1.6 times after 5½ months. The development of antibodies to *Salmonella breslau* under these conditions was determined in guinea pigs vaccinated 3, 12 and 19 months after irradiation. No disturbance of immunogenesis was found; thus antibody synthesis is only disturbed during acute radiation sickness. Decreased anti-infective properties of the tissues however, although not irreversible, persist during half of the life span of guinea pigs and white mice. Orig. art. has: 5 tables and 6 figures.

86-9-14/36

AUTHOR: Kiselev, P.P., Col.TITLE: Bombing the Small-Size Targets from a Fighter-Bomber  
(Bombometaniye s istrebitelya-bombardirovshchika po  
malorazmernym tselyam)

PERIODICAL: Vestnik Vozdushnogo Flota, 1957, Nr 9, pp. 40-46 (USSR)

ABSTRACT: In this article the author recommends that a sighting-aiming device should be installed in fighter-bombers, in order to train the flying personnel in accurate bombing of point targets and small-size targets. The bombing from medium and low altitudes at diving angles of 30 - 60° and at lead angles of 5 - 11° is difficult, because the point of aim, when ASP-3n sight is used, should be moved forward from the center of the target by the amount of lead allowance. In view of the fact that the aiming allowance changes within a wide range (from 200 - 800 m), when point targets or targets of small dimensions are bombed, the visual determination of the aiming point is associated with considerable errors. The device, suggested by the author, permits to aim directly at the center of the target regardless of its size. The device consists of

TITLE: On the approximation of analytic functions in the mean  
in a finite number of regions

PERIODICAL: Akademiya nauk Ukrayins'koyi RSR. Dopovidi, no. 1, 1963,  
6-9

TEXT: The author considers a region  $D$  of the complex  $z$ -plane, bounded by a closed rectifiable Jordan curve  $\Gamma$ . If a function  $f(z)$  is analytic at interior points of  $D$  and possesses in  $\bar{D}$  a  $k$ -th derivative  $f^{(k)}(z)$  belonging to class  $E_p$  in  $D$  and satisfying the generalized Lipschitz condition of order  $\alpha$  on  $\Gamma$ , the function is said to be of class  $E(k, p, \alpha)$ . A set  $E$  bounded by a finite number of mutually external smooth Jordan curves  $\Gamma_j$ ,  $j = 1, 2, \dots, v$  on each curve of which the angle  $\theta(s)$  which the tangent makes with the real axis has, considered as a function of the arc-length  $s$ , a modulus

of continuity  $j(h)$  which satisfies

$$\int_0^c \frac{j(h)}{h} dh < \infty \quad (1)$$

It is proved that if a function  $f(z)$  is of class  $E(k, p, \alpha)$ ,  $p > 1$ ,  $0 < \alpha \leq 1$  in such as set  $E$ , then there exist polynomials  $\Pi_n(z)$  of degree  $n$  which satisfy

$$\|f(z) - \Pi_n(z)\|_{\Gamma} = \left\{ \int_{\Gamma} |f(z) - \Pi_n(z)|^p |dz| \right\}^{1/p} < \frac{M_3}{n^{k+\alpha}}$$

where  $M_3$  is a constant which is dependent only on  $E$  and  $p$ . The proof is based on the use of a function  $w = \varphi_j(z)$  which effects a

AUTHOR: Kiselev, S., Sportsman 1st Rank (Sverdlovsk)

TITLE: New Sports Parachute (Novyy sportivnyy parashyut)

PERIODICAL: Kryl'ya rodiny, 1958, Nr 9, pp 24-25 (USSR)

ABSTRACT: The author discusses the essential features in a sports parachute and refers to the general opinion that at high altitudes a parachute requires an easily managed canopy to provide adequate speed in horizontal shifts. At low altitudes, the canopy of such a parachute should be able to develop greater or lesser speed when shifting in any direction at the will of the parachutist. It is also generally agreed that the T-2 parachute is well adapted for maneuvering and approaching a target from a rela-

AUTHOR: Kiselev, S., Master of Sports

TITLE: A New Sport Parachute

PERIODICAL: Kryl'ya rodiny, 1960, No. 9, pp. 20-21

TEXT: Having enumerated a number of shortcomings of the standard Soviet T-2 (T-2) sport parachute, the author praises the advantages of a double-slotted PT-1-2 sport parachute: a greater speed of horizontal movement and angular rotation, an elimination of sidewise "drift" of the canopy during turns, a higher suitability for jumps aiming at accuracy of landing at the target, etc. The canopy of this novel parachute is round, consisting of 28 conical panels, each one sewed together from four sections. It has a round central vent, reinforced upper and lower brims, 14 shroud lines running through the whole canopy in radial seams. The parachute has two L-shaped slots located between the 3d-5th and 24th-26th shroud lines (Fig. 1). The control shroud lines are 1,300 mm long, attached to shroud lines No. 5 and 24. By using the front harness straps it is possible to quickly turn about (to the left by using the right strap and vice versa). The use of the rear straps is not effective unless they are braced by ✓

two 2m-long additional shroud lines: one such line connects the shroud line No. 26 with the semi-ring of the right rear strap, the other connects the shroud line No. 3 with the semi-ring of the left rear strap. The pilot parachute is round; the parachute pack is made of a caprone cloth. Tested by a state commission, the novel parachute has shown the following characteristics: speed of descent 5.2m/sec., speed of horizontal movement in the air 3.5m/sec., one turn round the vertical axis 5-7 sec. The sensitivity of this parachute calls upon its user to be very attentive and capable of quickly evaluating his position with respect to the ground. There are 3 figures.

TITLE: Down-hand and all-position inert gas-shielded arc welding of avial alloy pipe joints

SOURCE: Svarochnoye proizvodstvo, no. 6, 1966, 34-35

TOPIC TAGS: welding, shielded arc welding, aluminum alloy, magnesium containing alloy, silicon containing alloy, alloy pipe welding, weld property

ABSTRACT: Annealed and aged pipes, 115x3.5 or 128x3.9 mm in diameter, from the avial-type aluminum alloy of the Al-Mg-Si system containing 0.90% Si and 0.65% Mn, were MIG welded with a consumable electrode either in argon atmosphere or in a mixture of argon with 60-70 He. X-ray inspection revealed that pipe joints welded in a fixed position had pores up to 0.6 mm in diameter and tungsten inclusions 0.2-0.3 mm in diameter, while down-hand welded joints, as a rule, had no defects. The welds made with the Ar-He mixture had a tensile strength of 19.7 kg/mm<sup>2</sup> and a bend angle of 86.3 deg; the corresponding figures for the welds made with argon were 17.3 kg/mm<sup>2</sup> and 59.5 deg. Welds made with the Ar-He mixture also had lower porosity. Generally, the strength of the gas-mixture welded joints was 70-80% of the strength of the base.

metals, compared with 65-70% for argon welded joints. Also, softening of the heat-affected zone was much less pronounced in gas-mixture welds. The higher strength of the gas-mixture welded joints is explained by a lower specific heat input, and the greater bend angle, by the higher homogeneity of welded metal. Prolonged aging at 100°C increased the weld tensile strength to 24.6-25 kg/mm<sup>2</sup>, but decreased the bend angle to 28-29.2 deg. In tests, all unaged joints failed in the heat-affected zone, but after aging at 100°C for 1000 hr the joints failed predominantly along the weld metal. This is because the weld metal strength is lower than the strength of the aged base metal and also because of weld defects. Orig. art. has: 2 figures and 1 table. [ND]

TITLE: Automatic welder, Class 21, No. 179402 18

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 5, 1966, 48

TOPIC TAGS: welder, butt welding, seam welding 14.

ABSTRACT: This Author Certificate presents an automatic welder, using a nonmelting electrode in a protective atmosphere for ring and seam pipe welding. The welder includes an inlet port, ring-shaped rotator, welding head, system of roller supports, mechanisms for moving and correcting the welding head, electrode wire supplies, programmed current switching, and remote control equipment. To permit welding of variable diameter pipe and welding of flanges and rings, the rotator is equipped with a mechanism for displacement in the vertical plane, allowing a rotator body angle of 0--105° with respect to the horizontal. The centering mechanism consists of a fixture which is equipped with grips and shimming rings and a conical screw-driven compensator (see Fig. 1). A second feature has two perpendicular worms as

TITLE: Pattern of distribution of residual surface stresses in welded plates of avial alloy

SOURCE: Svarochnoye proizvodstvo, no. 12, 1966, 6-8

TOPIC TAGS: metal stress, internal stress, weld evaluation, strain gage / Sv-AK-5 welding  
rod

ABSTRACT: The increasing use of avial-alloy-type structural elements and weldments of considerable thickness in which residual welding stresses combine with the scale factor as well as with the mechanical, chemical and structural heterogeneity of welded joints and the changes in plasticity of the material owing to aging processes, makes increasingly imperative an investigation of these stresses. Accordingly these stresses were measured in plates 30-, 40-, 70-, 90-, 140-, 220- and 300-mm thick of an avial type alloy containing 0.8-0.85% Si and 0.6-0.7% Mg in hardened and artificially aged state, with the aid of strain gages having a base of 5 mm and a resistance of the order of 50 ohm. The strain gauges were attached at intervals

of 100 mm each to the welded plates (which were 500 mm wide each half, and 500 and 1500 mm long) along the weld line in both directions from the center (in the direction of the principal axes of deformation). Findings: the pattern of distribution of residual surface stresses the welded joints of avial type plates differs from the pattern observed for low-carbon steels. Thus, in avial-type plates the residual welding stresses reach their maximum in the near-weld zone whereas in low-carbon steel plates these stresses reach their maximum at the weld center. This is attributable to the mechanical heterogeneity of the welded joints of avial-type alloys (the use of Sv-AK-5 welding rod, which contains 5% Si, and the softening of the base as well as to the features of formation of residual stresses, which are also determined by the thermophysical properties of the material: the high thermal conductivity of aluminum alloy leads to the elastic deformation of the metal in the near-weld zone. Orig. art. has: 5 figures.

TITLE: Mechanical properties of heavy welded avial-type alloy specimens

SOURCE: Avtomaticheskaya svarka, no. 5, 1966, 16-19

TOPIC TAGS: aluminum alloy, alloy weld, weld property, avial alloy

ABSTRACT: The effect of the size factor on the mechanical properties of heat-treatable avial-type aluminum-base alloy (0.74-0.90% Si, 0.59-0.70% Mg) welds and base metal has been studied. Specimens 10x10x100, 30x30x450, 40x40x500, 60x60x600, and 120x120x1000 mm (respective size factors 1, 3, 4, 6 and 12) were made from plates 40, 70, 90, 220 and 330 mm thick. Welding was done with a consumable SvAK-5 electrode in an argon-helium atmosphere. The base metal in the heat-treated condition (annealing and aging) had a tensile strength of 20-25 kg/mm<sup>2</sup>, a yield strength of 10-14 kg/mm<sup>2</sup>, and an elongation of 20-25%; corresponding figures for welded specimens were 16-19 kg/mm<sup>2</sup>, 8-10 kg/mm<sup>2</sup>, and 10-12%. Fracture in most cases was in the weld. Bend tests (on specimens with the Charpy-type notch) showed that with increasing size factor, the bend angle (measured at the appearance of the first crack)

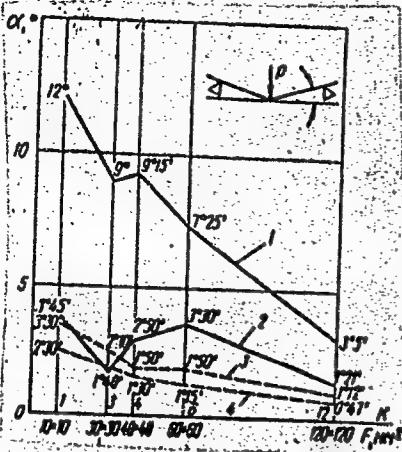

Fig. 1. Effect of the size factor on the bend angle of avial-type alloy base metal in the heat-treated condition (1) and aged at 130°C for 200 hr (2); and in as-welded alloy welds (3) aged at 130°C for 200 hr (4).

dropped. The values of bend angle in welded specimens were much lower than in base metal (see Fig. 1). Aging at 100 C for 1000 hr brings about a further drop in the ductility of welded specimens. After this treatment they failed in a brittle manner.

TITLE: A Hydraulic Device for the Scrap-Less Cold Rolling of Bar Stock for Making Keys

PERIODICAL: Mashinostroitel', 1959, Nr 5, pp 23-24 (USSR)

ABSTRACT: To cut down metal losses into chips, and the high machining costs in making keys, some plants are using cold rolling of bars in broaching machines. The rolled bars are then machined, so that there is still some machining and waste. The Vsesoyuznyy proyektno-tehnologicheskiy institut tyazhelogo mashinostroyeniya (All-Union Design and Technology Institute of Heavy Machine Building), jointly with the Mogilevskiy zavod pod'yemno-transportnogo oborudovaniya (Mogilev Materials Handling Machine Plant) have developed a special hydraulic device (Figure 2) for the "7510" broaching machine, with a 10-ton drawing effort. The exchangeable rollers of the device permit the obtaining of key bars of 8x10, 6x6 and 5x5 mm sections. The device is to be placed on the transition faceplate of the machine. The special chuck (Figure 3), fixed

Card 1/2

SOV/117-59-5-13/30

A Hydraulic Device for the Scrap-Less Cold Rolling of Bar Stock for Making Keys

in the machine slider, grips and pulls the rods in the rolling process. Design details are given. The application of the device at the Mogilev Plant has fully eliminated the forging and machining (planing and grinding) of keys, reduced by 25 to 30% the metal consumption, and improved the dimensions, accuracy and the mechanical properties of keys. There are 3 sets of diagrams.

TITLE: Welding thick plates of SAB-1 aluminum alloy 55

SOURCE: Avtomaticheskaya svarka, no. 7, 1965, 44-47 55 21

TOPIC TAGS: aluminum alloy, aluminum alloy thick plate, thick plate welding, edge groove geometry, welding electrode, weld metal property, heat treatment effect

ABSTRACT: Experiments have been made to develop an improved technique for welding thick plates of SAB-1 aluminum alloy, an age-hardenable alloy of the Al-Mg-Si system with Si:Mg > 1. Plates, 40, 80, and 140 mm thick, of SAB-1 alloy containing 0.81% Si and 0.48% Mg were inert-gas arc welded with a consumable electrode of the SvAK-5 type, 2, 4, or 5 mm in diameter, using a mixture of 30—40% Ar and 60—70% He for arc shielding. The use of helium made it possible to increase the temperature of the molten metal pool, to raise the voltage, and to ensure good weld formation. The best groove geometry was a double-V without root opening. In the experiments, the welding current was 450—520 amp, the arc voltage was 29—32 v, the Ar consumption

Card 1/2

L 00996-66

ACCESSION NR: AP5018699

was 30—35 l/min, and the He consumption was 50—60 l/min. The welding speed varied from 11.5 to 18.2 m/hr, and the number of passes was 6, 12—14, and 26—28 for plates 40, 80, and 140 mm, respectively. Welding with 4-mm electrode wire produced the least porous weld metal. Prior to heat treatment, the hardness of the heat-affected zone in 40-mm plates decreased by 15—18 HB compared with the parent metal, with the maximum decrease taking place at a distance of 12—15 mm from the fusion line. The corresponding figures for 80-mm plates were 10—12 HB and 8—10 mm, and for 140-mm plates, 5—8 HB and 5—6 mm. Subsequent heat treatment leveled to some extent the mechanical properties of the metal in the heat-affected zone, but did not improve them in the weld metal. Development of special electrode wire for welding SAB-1 type alloys is recommended to obtain welded joints which, after heat treatment, would have the strength of the parent metal. Orig. art. has: 5 figures and 3 tables.
